 - ▶ Signal change on pin
 - ▶ Action depends on context
 - ▶ # of edges arrived on pin
- ▶ Internal events e.g.:
 - ▶ Power failure

Interrupt Model

- ▶ **When an interrupt event occurs:**
 - ▶ Processor does an automatic procedure call
 - ▶ CALL automatically done to address for that interrupt
 - ▶ Push current PC, Jump to interrupt address
 - ▶ Each event has its own interrupt address
 - ▶ The global interrupt enable bit (in SREG) is automatically cleared
 - ▶ i.e. nested interrupts are disabled
 - ▶ SREG bit can be set to enable nested interrupts if desired
- ▶ **Interrupt procedure, aka “interrupt handler”**
 - ▶ Does whatever it needs to, then returns via RETI
 - ▶ The global interrupt enable bit is automatically set on RETI
 - ▶ One program instruction is always executed after RETI

Interrupts

- ▶ **Type 1 – Event is remembered when interrupt is disabled**
 - ▶ If interrupt is not enabled, flag is set
 - ▶ When interrupt is enabled again, interrupt takes place, and flag is reset
- ▶ **Type 2 – Event is not remembered when interrupt is disabled**
 - ▶ Signal level causes interrupt
 - ▶ If level occurs when interrupt is enabled, interrupt takes place
 - ▶ If interrupt is not enabled, and level goes away before the interrupt is enabled, nothing happens

Interrupt Model

- ▶ **Interrupt handler is invisible to program**
 - ▶ Except through side-effects, e. g. via flags or variables
 - ▶ Changes program timing
 - ▶ Can't rely on "dead-reckoning" using instruction timing
- ▶ **Must be written so they are invisible**
 - ▶ Cannot stomp on program state, e. g. registers
 - ▶ Save and restore any registers used
 - ▶ Including SREG

Interrupt Vectors

- ▶ Table in memory containing the first instruction of each interrupt handler
- ▶ Typically at program address 0

    // Using timer 2
    // Set to Normal mode, Pin OC0A disconnected

    // Interrupt every 256K/16M sec = 1/64 sec

Timer Example #2

    // Set compare register
